

# AI ASSISTANT CODING

## LAB-3.1

Name : ENDLA ESHWAR PRASAD

Roll No : 2303A52377

Batch No : 33

### Experiment – Prompt Engineering Techniques

#### Task Description

Design and refine prompts using different prompting strategies to generate Python programs for basic computational problems.

#### Question 1: Zero-Shot Prompting (Palindrome Number Program)

Write a zero-shot prompt (without providing any examples) to generate a Python function that checks whether a given number is a palindrome.

Task:

- Record the AI-generated code.
- Test the code with multiple inputs.
- Identify any logical errors or missing edge-case handling.

#### Prompt Used :

Write a Python function that checks whether a given integer number is a palindrome. The function should return True if the number reads the same forward and backward, otherwise return False.

#### AI-Refactored Code :

```
def is_palindrome_number(number: int) -> bool:
```

```
    """
```

```
    Checks if a given integer number is a palindrome.
```

```
    A number is a palindrome if it reads the same forward and backward.
```

```
    Args:
```

```
        number (int): The integer number to check.
```

Returns:

bool: True if the number is a palindrome, False otherwise.

"""

if not isinstance(number, int):

raise TypeError("Input must be an integer.")

# Convert the integer to a string to easily reverse it

num\_str = str(number)

# Compare the string with its reverse

return num\_str == num\_str[::-1]

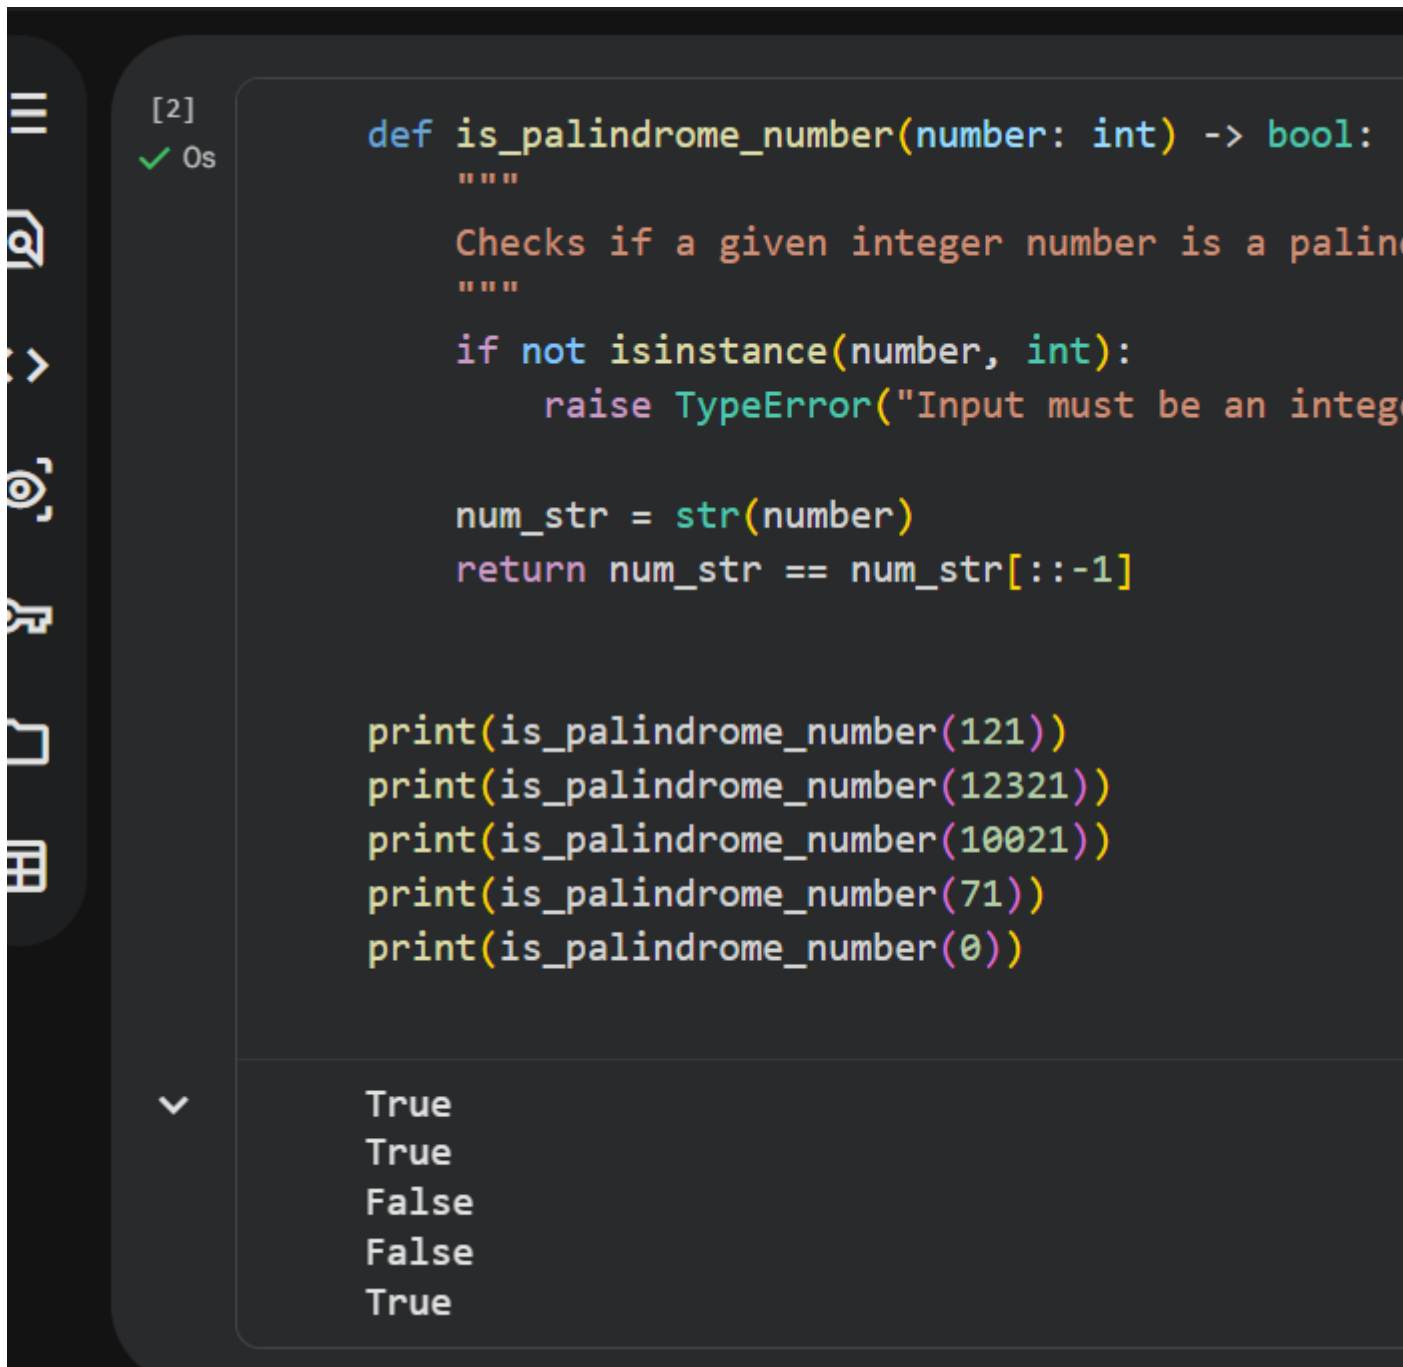

print(is\_palindrome\_number(121))

print(is\_palindrome\_number(12321))

print(is\_palindrome\_number(10021))

print(is\_palindrome\_number(71))

print(is\_palindrome\_number(0))

The image shows a code editor interface with a dark theme. On the left, there is a sidebar with icons for file explorer, search, and other tools. The main area displays a Python function `is_palindrome_number` that takes an integer and returns a boolean. The function includes a docstring, a type check, and a string reversal logic. Below the function, there are five print statements testing the function with the values 121, 12321, 10021, 71, and 0. The output of these tests is shown in a separate pane at the bottom, displaying the results: True, True, False, False, and True.

```

def is_palindrome_number(number: int) -> bool:
    """
    Checks if a given integer number is a palindrome.
    """
    if not isinstance(number, int):
        raise TypeError("Input must be an integer")

    num_str = str(number)
    return num_str == num_str[::-1]

print(is_palindrome_number(121))
print(is_palindrome_number(12321))
print(is_palindrome_number(10021))
print(is_palindrome_number(71))
print(is_palindrome_number(0))

True
True
False
False
True
```

## Question 2: One-Shot Prompting (Factorial Calculation)

Write a one-shot prompt by providing one input-output example and ask the AI to generate a Python function to compute the factorial of a given number.

Example:

Input: 5 → Output: 120

Task:

- Compare the generated code with a zero-shot solution.
- Examine improvements in clarity and correctness.

### **Prompt Used :**

Write a Python function to compute the factorial of a given non-negative integer.

### **CODE:**

```
def factorial(n: int) -> int:
```

```
    """
```

```
    Computes the factorial of a given non-negative integer.
```

```
    Args:
```

```
        n (int): The non-negative integer for which to compute the factorial.
```

```
    Returns:
```

```
        int: The factorial of n.
```

```
    Raises:
```

```
        ValueError: If n is a negative integer.
```

```
        TypeError: If n is not an integer.
```

```
    """
```

```
    if not isinstance(n, int):
```

```
        raise TypeError("Input must be an integer.")
```

```
    if n < 0:
```

```
        raise ValueError("Factorial is not defined for negative numbers.")
```

```
    if n == 0:
```

```
        return 1
```

```
    else:
```

```
        result = 1
```

```
for i in range(1, n + 1):
```

```
    result *= i
```

```
return result
```

```
print(factorial(5))
```

```
print(factorial(10))
```

```
print(factorial(0))
```

```
def factorial(n: int) -> int:
```

```
    """
```

```
    Computes the factorial of a given non-negative integer.
```

```
    """
```

```
    if not isinstance(n, int):
```

```
        raise TypeError("Input must be an integer.")
```

```
    if n < 0:
```

```
        raise ValueError("Factorial is not defined for negative numbers.")
```

```
    if n == 0:
```

```
        return 1
```

```
    else:
```

```
        result = 1
```

```
        for i in range(1, n + 1):
```

```
            result *= i
```

```
        return result
```

```
print(factorial(5))
```

```
print(factorial(10))
```

```
print(factorial(0))
```

```
... 120
    3628800
    1
```

### Question 3: Few-Shot Prompting (Armstrong Number Check)

Write a few-shot prompt by providing multiple input-output examples to guide the AI in generating a Python function to check whether a given number is an Armstrong number.

Examples:

- Input: 153 → Output: Armstrong Number
- Input: 370 → Output: Armstrong Number
- Input: 123 → Output: Not an Armstrong Number

Task:

- Analyze how multiple examples influence code structure and accuracy.
- Test the function with boundary values and invalid inputs.

### Prompts Used :

Write a Python function to check whether a given integer is an Armstrong number.

### CODE:

```
def is_armstrong_number(number: int) -> bool:
```

```
    """
```

```
    Checks if a given integer number is an Armstrong number.
```

```
    An Armstrong number is a number that is the sum of its own digits
    each raised to the power of the number of digits.
```

```
    Args:
```

```
        number (int): The integer number to check.
```

```
    Returns:
```

bool: True if the number is an Armstrong number, False otherwise.

Raises:

TypeError: If the input is not an integer.

ValueError: If the input is a negative integer (Armstrong numbers are typically defined for positive integers).

```
"""
```

```
if not isinstance(number, int):
```

```
    raise TypeError("Input must be an integer.")
```

```
if number < 0:
```

```
    raise ValueError("Armstrong numbers are typically defined for non-negative integers.")
```

```
# Convert the number to a string to easily access its digits and count them
```

```
num_str = str(number)
```

```
num_digits = len(num_str)
```

```
sum_of_powers = 0
```

```
for digit_char in num_str:
```

```
    digit = int(digit_char)
```

```
    sum_of_powers += digit ** num_digits
```

```
return sum_of_powers == number
```

```
print(is_armstrong_number(153))
```

```
print(is_armstrong_number(370))
```

```
print(is_armstrong_number(371))
```

```
print(is_armstrong_number(407))
```

```
print(is_armstrong_number(1634))
```

```
print(is_armstrong_number(8208))
```

```
print(is_armstrong_number(9474))
```

```
def is_armstrong_number(number: int) -> bool:
    """
    Checks if a given integer number is an Armstrong number
    """
    if not isinstance(number, int):
        raise TypeError("Input must be an integer.")
    if number < 0:
        raise ValueError("Armstrong numbers are typically d

    num_str = str(number)
    num_digits = len(num_str)

    sum_of_powers = 0
    for digit_char in num_str:
        digit = int(digit_char)
        ⚡ sum_of_powers += digit ** num_digits
    return sum_of_powers == number
print(is_armstrong_number(153))
print(is_armstrong_number(370))
print(is_armstrong_number(371))
print(is_armstrong_number(407))
print(is_armstrong_number(1634))
print(is_armstrong_number(8208))
print(is_armstrong_number(9474))
```

```
... True
    True
    True
    True
    True
    True
    True
```

## Question 4: Context-Managed Prompting (Optimized Number Classification)

Design a context-managed prompt with clear instructions and constraints to generate an optimized Python program that classifies a number as prime, composite, or neither.

### Prompt:

*You are an expert Python developer writing optimized and readable code.*

**Task:** Write a Python program that classifies a given integer number as **Prime**, **Composite**, or **Neither**.

*Rules & Constraints:*

- If the number is less than or equal to 1, classify it as **Neither**.
- A **Prime** number has exactly two distinct positive divisors.
- A **Composite** number has more than two positive divisors.
- Use an optimized approach by checking divisibility only up to  $\sqrt{n}$ .
- The program must handle invalid inputs gracefully.
- Output must be one of the following strings only: "Prime", "Composite", or "Neither".
- Write clean, efficient, and well-commented Python code.

### CODE:

```
def classify_number(n):  
    if not isinstance(n, int):  
        return "Neither"  
  
    if n <= 1:  
        return "Neither"  
  
    for i in range(2, int(n ** 0.5) + 1):  
        if n % i == 0:  
            return "Composite"
```

```
return "Prime"
```

```
def classify_number(n):  
    if not isinstance(n, int):  
        return "Neither"  
  
    if n <= 1:  
        return "Neither"  
  
    for i in range(2, int(n ** 0.5) + 1):  
        if n % i == 0:  
            return "Composite"  
  
    return "Prime"  
print(classify_number(7))  
print(classify_number(10))  
print(classify_number(17))  
print(classify_number(1))
```

```
Prime  
Composite  
Prime  
Neither
```

## Conclusion :

This experiment demonstrated how different prompting techniques influence AI-generated code quality. Zero-shot prompting produced basic solutions, while one-shot and few-shot prompting improved clarity and accuracy through examples. Context-managed prompting delivered the most optimized and reliable results by clearly defining constraints and expectations. Overall, effective prompt design significantly enhances the correctness, efficiency, and robustness of AI-assisted coding.
